DESCRIPTION OF TREATMENT INTERVENTION

Name of product, its strength and dosage form (eg. EPIDOLEX/ EPIDIOLEX 100 mg/ml (10%) orally oral solution), dosage regimen and duration of treatment

EPIDIOLEX/EPIDYOLEX 100MG, 10 ML 4ML/ML

ANNEX 2 for Approval - DESCRIPTION AND USE

Nomenclature tables are abbreviated (Adapted Validated 03)

- Nomenclature: Mental nomenclature is used for all anatomical systems functions to increase survival, recognizability, and communication between all health professionals.
- Anatomy: Anatomy is the study of the structure of the body. Anatomy is divided into gross anatomy and microscopic anatomy.
- The management of disease is called physician care and includes all the actions taken to try to improve the health of a patient. Physician care includes diagnosis, treatment, and prevention of disease. Physician care is also called medical care, health care, or healthcare. Physician care is the act of preventing or treating the illness of a person.

WARNINGS AND PRECAUTIONS

- Short-term preparations (4 weeks)
- Long-term preparations (4 weeks to 3 months): Long-term preparations (4 weeks to 3 months) are used for the treatment of chronic conditions that require ongoing medical attention. Examples of long-term preparations include medications for diabetes, hypertension, and asthma.

CONTRAINDICATIONS

- Hypersensitivity: Medicines are contraindicated in patients with a known history of hypersensitivity to the medicine or any of its excipients.
- Pregnancy: Medicines are contraindicated in pregnant women if they are known to cause harm to the developing fetus.
- Breastfeeding: Medicines are contraindicated in breastfeeding women if they are known to pass into breast milk and cause harm to the baby.
- Drug interactions: Medicines are contraindicated in patients who are taking other medicines that may interact with them and cause serious side effects.
- Underlying medical conditions: Medicines are contraindicated in patients with certain underlying medical conditions that may make them more likely to experience serious side effects.

ADVERSE REACTIONS

Adverse reactions are unwanted effects that occur when a medicine is taken as directed. They can range from mild to severe and can affect any part of the body. Some common adverse reactions include nausea, vomiting, diarrhea, headache, dizziness, and rash.

DRUG INTERACTIONS

Drug interactions occur when one medicine affects the way another medicine works. This can lead to increased or decreased effects of the medicines, or even new and unexpected side effects. Some common drug interactions include those between antibiotics and birth control pills, and between blood thinners and aspirin.

USE IN SPECIFIC POPULATIONS

Some medicines are not safe for use in certain populations, such as pregnant women, children, or people with certain medical conditions. It is important to talk to your doctor about any medicines you are taking before you start taking a new medicine.

OVERDOSAGE

Overdosage occurs when too much of a medicine is taken. This can be dangerous and even fatal. Symptoms of overdosage vary depending on the medicine taken, but can include nausea, vomiting, diarrhea, dizziness, confusion, and seizures.

DESCRIPTION

Description tables are abbreviated (Adapted Validated 03)

- Description: The description of a medicine includes its chemical structure, physical properties, and pharmacological effects.
- Chemical structure: The chemical structure of a medicine is the arrangement of atoms in its molecules. This structure determines the medicine's properties and how it interacts with the body.
- Physical properties: The physical properties of a medicine include its color, odor, taste, and solubility. These properties can affect how the medicine is absorbed and distributed in the body.
- Pharmacological effects: The pharmacological effects of a medicine are the changes it causes in the body. These effects can be beneficial or harmful.

CLINICAL PHARMACOLOGY

Clinical pharmacology tables are abbreviated (Adapted Validated 03)

- Pharmacokinetics: Pharmacokinetics is the study of how the body affects a medicine. It includes how the medicine is absorbed, distributed, metabolized, and excreted.
- Pharmacodynamics: Pharmacodynamics is the study of how a medicine affects the body. It includes the medicine's mechanism of action, its therapeutic effects, and its side effects.
- Drug interactions: Drug interactions occur when one medicine affects the way another medicine works. This can lead to increased or decreased effects of the medicines, or even new and unexpected side effects.

CLINICAL STUDIES

Clinical studies tables are abbreviated (Adapted Validated 03)

- Phase 1 clinical trials: Phase 1 clinical trials are the first stage of testing a new medicine in humans. They are typically small studies that involve a few dozen healthy volunteers.
- Phase 2 clinical trials: Phase 2 clinical trials are the second stage of testing a new medicine in humans. They are typically larger studies that involve several hundred patients with the condition that the medicine is intended to treat.
- Phase 3 clinical trials: Phase 3 clinical trials are the third stage of testing a new medicine in humans. They are typically large studies that involve several thousand patients with the condition that the medicine is intended to treat.
- Phase 4 clinical trials: Phase 4 clinical trials are the fourth stage of testing a new medicine in humans. They are typically conducted after the medicine has been approved for use by the FDA.

HOW SUPPLIED/STORAGE AND HANDLING

How supplied tables are abbreviated (Adapted Validated 03)

- How supplied: The how supplied section of a medicine's package insert describes the different forms in which the medicine is available, such as tablets, capsules, liquids, or injections.
- Storage and handling: The storage and handling section of a medicine's package insert describes how the medicine should be stored and handled to maintain its quality and safety.

PATIENT COUNSELING INFORMATION

Patient counseling information tables are abbreviated (Adapted Validated 03)

- Patient counseling information: The patient counseling information section of a medicine's package insert provides information that patients should know about the medicine, such as how to take it, what to expect, and what to do if they have any questions or concerns.

* Sections or subsections omitted from the full prescribing information are not listed.

Text 2 for FULL PRESCRIBING INFORMATION: CONTENTS:

Revised: 07/2021

1 INDICATION AND USAGE

EPIDIOLEX is indicated for the treatment of seizures associated with Dravet syndrome, seizures associated with tuberous sclerosis complex, and seizures associated with Lennox-Gastaut syndrome in patients 1 year of age and older.

2 DOSAGE AND ADMINISTRATION

2.1 Dravet Syndrome

The recommended dose for patients with Dravet syndrome is 5 mg/kg/day twice daily (10 mg/kg/day total daily dose). Some patients may require a dose of 10 mg/kg twice daily (20 mg/kg/day total daily dose) to achieve optimal seizure control. Titrate to the dose that provides optimal seizure control with tolerable adverse reactions. Titrate dose as described in Section 2.4.

2.2 Seizures Associated with Tuberous Sclerosis Complex

The recommended dose for patients with tuberous sclerosis complex is 25 mg/kg/day twice daily (50 mg/kg total daily dose). Titrate dose as described in Section 2.4.

2.3 Lennox-Gastaut Syndrome

The recommended dose for patients with Lennox-Gastaut syndrome is 2.5 mg/kg twice daily (5 mg/kg total daily dose). Titrate dose as described in Section 2.4.

2.4 Titration Schedule

Titrate dose to the recommended dose over the first 3 weeks as follows:

- Week 1: 2.5 mg/kg twice daily (5 mg/kg total daily dose)
- Week 2: 5 mg/kg twice daily (10 mg/kg total daily dose)
- Week 3: Recommended dose (see Sections 2.1, 2.2, and 2.3)

2.5 Preparation and Administration

Shake bottle well before each dose. Administer EPIDIOLEX orally using the supplied oral dosing syringe. Do not substitute other oral dosing devices for the supplied oral dosing syringe. Administer EPIDIOLEX with food. Administration with food increases the exposure of cannabidiol. Dose EPIDIOLEX based on the recommended dosage and titration schedule.

3 CONTRAINDICATIONS

Hypersensitivity to cannabidiol or to the excipients.

4 WARNINGS AND PRECAUTIONS

4.1 Hepatotoxicity

Drug-induced liver injury, including cases with features of autoimmune hepatitis, has been observed in patients treated with EPIDIOLEX. Monitor patients for signs and symptoms of liver injury. Discontinue EPIDIOLEX if drug-induced liver injury is suspected.

4.2 Concomitant use with Valproate

Concomitant use of EPIDIOLEX with valproate increases the risk of hepatotoxicity. Consider dose reduction of valproate when initiating EPIDIOLEX.

4.3 Somnolence and Sedation

Somnolence and sedation have been reported in patients given cannabidiol, including EPIDIOLEX. Concomitant use of EPIDIOLEX with clobazam may increase the risk of somnolence and sedation. Consider dose reduction of clobazam when initiating EPIDIOLEX.

4.4 Suicidal Behavior and Ideation

Antiepileptic drugs, including EPIDIOLEX, increase the risk of suicidal behavior or ideation. Monitor patients for the emergence or worsening of depression, suicidal thoughts or behavior, or any unusual changes in mood or behavior.

4.5 Withdrawal of Antiepileptic Drugs

Withdrawal of antiepileptic drugs may precipitate status epilepticus. Withdraw gradually unless safety concerns require more rapid withdrawal.

5 ADVERSE REACTIONS

5.1 Clinical Trials Experience

Because clinical trials are conducted under widely varying conditions, adverse reaction rates observed in the clinical trials of a drug cannot be directly compared to rates in the clinical trials of another drug and may not reflect the rates observed in practice.

Dravet Syndrome

The safety of EPIDIOLEX was evaluated in 516 patients with Dravet syndrome who participated in 3 placebo-controlled clinical trials and 2 open-label clinical trials. The most common adverse reactions (≥ 10% and greater than placebo) were somnolence, decreased appetite, pyrexia, vomiting, diarrhea, lethargy, abnormal behavior, upper respiratory tract infection, insomnia, rash, and ataxia.

Seizures Associated with Tuberous Sclerosis Complex

The safety of EPIDIOLEX was evaluated in 224 patients with seizures associated with tuberous sclerosis complex who participated in 2 placebo-controlled clinical trials and 1 open-label clinical trial. The most common adverse reactions (≥ 10% and greater than placebo) were pyrexia, upper respiratory tract infection, vomiting, diarrhea, rash, and urinary tract infection.

Lennox-Gastaut Syndrome

The safety of EPIDIOLEX was evaluated in 308 patients with Lennox-Gastaut syndrome who participated in 3 placebo-controlled clinical trials and 1 open-label clinical trial. The most common adverse reactions (≥ 10% and greater than placebo) were somnolence, decreased appetite, diarrhea, vomiting, pyrexia, convulsion, lethargy, status epilepticus, upper respiratory tract infection, abnormal behavior, rash, and insomnia.

Adverse Reactions Leading to Discontinuation of Treatment

In clinical trials, approximately 5% of patients discontinued treatment with EPIDIOLEX because of adverse reactions. The most common adverse reactions leading to discontinuation were somnolence, decreased appetite, vomiting, and diarrhea.

Dose Reduction or Interruption Due to Adverse Reactions

In clinical trials, approximately 30% of patients had a dose reduction or interruption because of adverse reactions. The most common adverse reactions leading to dose reduction or interruption were somnolence, decreased appetite, vomiting, and diarrhea.

Laboratory Abnormalities

In clinical trials, elevations of transaminases (ALT or AST) ≥ 3 times the upper limit of normal were observed in 4% of patients receiving EPIDIOLEX and 1% of patients receiving placebo. Elevations of transaminases ≥ 3 times the upper limit of normal were observed in 1% of patients receiving EPIDIOLEX and 0% of patients receiving placebo when EPIDIOLEX was administered without valproate. When EPIDIOLEX was administered with valproate, elevations of transaminases ≥ 3 times the upper limit of normal were observed in 7% of patients receiving EPIDIOLEX and 2% of patients receiving placebo.

5.2 Postmarketing Experience

The following adverse reactions have been identified during post-approval use of EPIDIOLEX. Because these reactions are reported voluntarily from a population of uncertain size, it is not always possible to reliably estimate their frequency or establish a causal relationship to drug exposure.

Hepatic enzyme elevations, hepatitis, hepatic failure, and liver injury

6 DRUG INTERACTIONS

6.1 Effect of Concomitant Medications on EPIDIOLEX

Concomitant use of EPIDIOLEX with clobazam increases the exposure of clobazam and its active metabolite N-desmethylclobazam. Consider dose reduction of clobazam when initiating EPIDIOLEX.

Concomitant use of EPIDIOLEX with valproate increases the exposure of the active metabolite of valproate, 4-ene-valproic acid. Consider dose reduction of valproate when initiating EPIDIOLEX.

Concomitant use of EPIDIOLEX with rifampin decreases the exposure of cannabidiol. Dose adjustment of EPIDIOLEX may be necessary when coadministered with rifampin.

Concomitant use of EPIDIOLEX with strong inducers of UGT enzymes (such as carbamazepine) decreases the exposure of cannabidiol. Dose adjustment of EPIDIOLEX may be necessary when coadministered with strong inducers of UGT enzymes.

6.2 Effect of EPIDIOLEX on Concomitant Medications

Concomitant use of EPIDIOLEX with clobazam increases the exposure of clobazam. Reduce the dosage of clobazam by one-half when starting EPIDIOLEX. Subsequent dose adjustments should be based on clinical response.

Concomitant use of EPIDIOLEX with valproate increases the exposure of the active metabolite of valproate, 4-ene-valproic acid. Consider dose reduction of valproate when initiating EPIDIOLEX.

Concomitant use of EPIDIOLEX with rifampin decreases the exposure of cannabidiol. Dose adjustment of EPIDIOLEX may be necessary when coadministered with rifampin.

Concomitant use of EPIDIOLEX with strong inducers of UGT enzymes (such as carbamazepine) decreases the exposure of cannabidiol. Dose adjustment of EPIDIOLEX may be necessary when coadministered with strong inducers of UGT enzymes.

7 USE IN SPECIFIC POPULATIONS

7.1 Pregnancy

There are no adequate and well-controlled studies in pregnant women. Because animal reproduction studies are not always predictive of human response, EPIDIOLEX should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

In animal reproduction studies, administration of cannabidiol to pregnant rats and rabbits during the period of organogenesis resulted in embryofetal developmental toxicity (decreased fetal body weights, increased incidences of fetal malformations and variations) at exposures (AUC) approximately 0.5 and 0.2 times, respectively, the exposure in humans at the maximum recommended human dose (MRHD) of 20 mg/kg/day. Administration of cannabidiol to pregnant rats during the period of organogenesis and lactation resulted in decreased offspring viability and growth at exposures approximately 0.5 times the exposure in humans at the MRHD.

7.2 Lactation

Risk Summary

Based on limited information, cannabidiol is present in human milk. No data are available on the effects of cannabidiol on the breastfed infant or on milk production. Because of the potential for serious adverse reactions in breastfed infants, advise patients that breastfeeding is not recommended during treatment with EPIDIOLEX.

7.3 Females and Males of Reproductive Potential

Based on animal data, EPIDIOLEX may impair fertility in females and males of reproductive potential. It is not known if these effects on fertility are reversible.

7.4 Pediatric Use

The safety and effectiveness of EPIDIOLEX have been established in pediatric patients 1 year of age and older with seizures associated with Dravet syndrome, seizures associated with tuberous sclerosis complex, and seizures associated with Lennox-Gastaut syndrome. Use of EPIDIOLEX in these patients is supported by evidence from adequate and well-controlled studies in adults with additional safety data in pediatric patients with Dravet syndrome, tuberous sclerosis complex, and Lennox-Gastaut syndrome. The safety and effectiveness of EPIDIOLEX have not been established in pediatric patients less than 1 year of age.

7.5 Geriatric Use

Clinical studies of EPIDIOLEX did not include sufficient numbers of subjects aged 65 and over to determine whether they respond differently from younger subjects.

7.6 Hepatic Impairment

Avoid use of EPIDIOLEX in patients with moderate or severe hepatic impairment (Child-Pugh B or C). Dose adjustment is not recommended for patients with mild hepatic impairment (Child-Pugh A).

8 DRUG ABUSE AND DEPENDENCE

8.1 Controlled Substance

EPIDIOLEX contains cannabidiol derived from cannabis. It is not scheduled under the Controlled Substances Act.

8.2 Abuse

Cannabidiol has a low potential for abuse. Cannabidiol has been evaluated in humans for its potential for abuse and dependence. Cannabidiol was not self-administered by humans in a manner indicative of abuse potential. Cannabidiol did not produce withdrawal symptoms when discontinued abruptly.

9 OVERDOSAGE

9.1 Human Experience

Somnolence, sedation, and decreased appetite were observed in patients given cannabidiol, including EPIDIOLEX, at doses 3 times the recommended dose.

9.2 Management of Overdosage

Treatment of overdose should consist of general supportive measures including monitoring of vital signs and observation of the clinical status of the patient. Consider contacting a poison control center for additional information on the treatment of overdose.

10 DESCRIPTION

EPIDIOLEX (cannabidiol) oral solution is a clear to slightly hazy, colorless to slightly yellow solution. EPIDIOLEX contains cannabidiol, a cannabinoid with anticonvulsant activity. Cannabidiol is a non-psychoactive cannabinoid. Cannabidiol is not a tetrahydrocannabinol (THC) analog. It has the chemical name 2-[(1R,6R)-3-methyl-6-(1-methylethenyl)-2-cyclohexen-1-yl]-5-pentyl-1,3-benzenediol and the molecular formula $C_{21}H_{30}O_2$. Its structural formula is:

Cannabidiol has a molecular weight of 314.46 g/mol. It is lipophilic and practically insoluble in water.

EPIDIOLEX is supplied as a 100 mg/mL oral solution. Each mL of EPIDIOLEX contains 100 mg cannabidiol. EPIDIOLEX also contains the following inactive ingredients: ethanol, glycerol, propylene glycol, sucrose, and water.

11 CLINICAL PHARMACOLOGY

11.1 Mechanism of Action

The mechanism by which cannabidiol exerts its therapeutic effects is unknown. The effects of cannabidiol may be mediated through non-CB1, non-CB2 receptor mechanisms.

11.2 Pharmacodynamics

The relationship between the dose-normalized plasma concentration of cannabidiol and the QTcF interval was evaluated in a thorough QT study in healthy subjects. Cannabidiol concentrations up to approximately 3 times the concentrations observed at the maximum recommended dose of 20 mg/kg/day did not prolong the QTcF interval to any clinically relevant extent.

11.3 Pharmacokinetics

Steady-state plasma concentrations of cannabidiol are achieved within 2 weeks of administration of EPIDIOLEX. Cannabidiol exposure increases in a dose-proportional manner. Cannabidiol accumulates with multiple dosing with a median accumulation ratio of 3.1. Cannabidiol is highly bound (94% to 95%) to plasma proteins in vitro. The median time to peak plasma concentration was 4 hours in the fasted state and 5 hours when administered with a high-fat meal. Cannabidiol is eliminated with a terminal half-life of approximately 56 hours.

Metabolism

Cannabidiol undergoes extensive oxidative metabolism, primarily by CYP2C19, CYP3A4, and CYP2C9. Cannabidiol is also a reversible inhibitor of CYP2C19, CYP2C9, and CYP3A4 in vitro.

Excretion

Following administration of cannabidiol, approximately 34% of the dose is excreted in urine and 66% in feces. Unchanged cannabidiol is not detected in urine and accounts for 2% of the dose in feces.

Specific Populations

No clinically significant differences in the pharmacokinetics of cannabidiol were observed based on age (2 to 55 years), body weight, or sex.

Hepatic Impairment

In a study of subjects with moderate hepatic impairment (Child-Pugh B), the dose-normalized exposure of cannabidiol was approximately 4.5 times higher than in subjects with normal hepatic function. The pharmacokinetics of cannabidiol in subjects with mild hepatic impairment (Child-Pugh A) were similar to those in subjects with normal hepatic function.

Drug Interactions

In vitro data suggest that cannabidiol may inhibit the activity of UGT1A9. Cannabidiol is a reversible inhibitor of CYP2C19, CYP2C9, and CYP3A4 in vitro. Cannabidiol is also a substrate of CYP2C19, CYP2C9, and CYP3A4.

Clobazam and N-desmethylclobazam

Concomitant administration of clobazam 10 mg twice daily with EPIDIOLEX 10 mg/kg twice daily increased the steady-state C_{max} and AUC of clobazam by 50% and 74%, respectively, and increased the steady-state C_{max} and AUC of N-desmethylclobazam by 1.6-fold and 2.1-fold, respectively. Concomitant administration of clobazam 10 mg twice daily with EPIDIOLEX 20 mg/kg twice daily increased the steady-state C_{max} and AUC of clobazam by 60% and 92%, respectively, and increased the steady-state C_{max} and AUC of N-desmethylclobazam by 1.7-fold and 2.3-fold, respectively.

Valproate

Concomitant administration of valproate 15 mg/kg/day with EPIDIOLEX 5 mg/kg twice daily increased the steady-state C_{max} and AUC of 4-ene-valproic acid by 1.6-fold and 2.1-fold, respectively. Concomitant administration of valproate 15 mg/kg/day with EPIDIOLEX 10 mg/kg twice daily increased the steady-state C_{max} and AUC of 4-ene-valproic acid by 2.5-fold and 3.2-fold, respectively.

Rifampin

In a study in healthy subjects, concomitant administration of rifampin 600 mg once daily for 8 days with EPIDIOLEX 10 mg/kg twice daily decreased the dose-normalized C_{max} and AUC of cannabidiol by 95% and 85%, respectively. Concomitant administration of rifampin 600 mg once daily for 8 days with EPIDIOLEX 20 mg/kg twice daily decreased the dose-normalized C_{max} and AUC of cannabidiol by 95% and 87%, respectively.

Strong Inducers of UGT Enzymes

Concomitant administration of strong inducers of UGT enzymes (such as carbamazepine) decreases the exposure of cannabidiol. Dose adjustment of EPIDIOLEX may be necessary when coadministered with strong inducers of UGT enzymes.

12 CLINICAL STUDIES

12.1 Dravet Syndrome

The efficacy of EPIDIOLEX as adjunctive therapy for the treatment of seizures associated with Dravet syndrome was established in 3 randomized, double-blind, placebo-controlled clinical trials (Trial 1, Trial 2, and Trial 3) in patients 2 to 18 years of age. Patients had a diagnosis of Dravet syndrome and had uncontrolled seizures despite treatment with stiripentol, valproate, clobazam, and other medications.

Trial 1 (Study 1) was a 14-week trial that randomized 120 patients to receive EPIDIOLEX 10 mg/kg/day, EPIDIOLEX 20 mg/kg/day, or placebo. Patients had a mean baseline frequency of 12.4 convulsive seizures per 28 days. The primary endpoint was the change from baseline in convulsive seizure frequency per 28 days. Trial 2 (Study 2) was a 15-week trial that randomized 199 patients to receive EPIDIOLEX 10 mg/kg/day, EPIDIOLEX 20 mg/kg/day, or placebo. Patients had a mean baseline frequency of 15.9 convulsive seizures per 28 days. The primary endpoint was the change from baseline in convulsive seizure frequency per 28 days. Trial 3 (Study 3) was a 14-week trial that randomized 212 patients to receive EPIDIOLEX 10 mg/kg/day, EPIDIOLEX 20 mg/kg/day, or placebo. Patients had a mean baseline frequency of 12.6 convulsive seizures per 28 days. The primary endpoint was the change from baseline in convulsive seizure frequency per 28 days.

The addition of EPIDIOLEX 10 mg/kg/day or EPIDIOLEX 20 mg/kg/day to stiripentol, valproate, clobazam, and other medications resulted in a greater reduction in convulsive seizure frequency per 28 days compared to placebo. The median percent reduction from baseline in convulsive seizure frequency per 28 days was 39% for EPIDIOLEX 10 mg/kg/day, 43% for EPIDIOLEX 20 mg/kg/day, and 13% for placebo in Trial 1; 37% for EPIDIOLEX 10 mg/kg/day, 54% for EPIDIOLEX 20 mg/kg/day, and 17% for placebo in Trial 2; and 22% for EPIDIOLEX 10 mg/kg/day, 42% for EPIDIOLEX 20 mg/kg/day, and 9% for placebo in Trial 3. The median reduction in convulsive seizure frequency per 28 days was statistically significantly greater for EPIDIOLEX 20 mg/kg/day than placebo in Trial 1 and Trial 2. The median reduction in convulsive seizure frequency per 28 days was statistically significantly greater for EPIDIOLEX 10 mg/kg/day than placebo in Trial 3.

The percentage of patients who had a reduction in convulsive seizure frequency per 28 days of 50% or greater was 43% for EPIDIOLEX 10 mg/kg/day, 49% for EPIDIOLEX 20 mg/kg/day, and 27% for placebo in Trial 1; 36% for EPIDIOLEX 10 mg/kg/day, 62% for EPIDIOLEX 20 mg/kg/day, and 14% for placebo in Trial 2; and 30% for EPIDIOLEX 10 mg/kg/day, 42% for EPIDIOLEX 20 mg/kg/day, and 15% for placebo in Trial 3. The median treatment duration was 14 weeks for EPIDIOLEX 10 mg/kg/day, 14 weeks for EPIDIOLEX 20 mg/kg/day, and 14 weeks for placebo in Trial 1; 15 weeks for EPIDIOLEX 10 mg/kg/day, 15 weeks for EPIDIOLEX 20 mg/kg/day, and 14 weeks for placebo in Trial 2; and 14 weeks for EPIDIOLEX 10 mg/kg/day, 14 weeks for EPIDIOLEX 20 mg/kg/day, and 14 weeks for placebo in Trial 3.

Figure 1: Percent Reduction in Convulsive Seizure Frequency per 28 Days in Patients with Dravet Syndrome Treated with Adjunctive EPIDIOLEX 10 mg/kg/day, EPIDIOLEX 20 mg/kg/day, or Placebo

Figure 2: The Kaplan-Meier plot for the time to 50% reduction in convulsive seizure frequency per 28 days in patients with Dravet syndrome treated with adjunctive EPIDIOLEX 10 mg/kg/day, EPIDIOLEX 20 mg/kg/day, or placebo. The median time to 50% reduction in convulsive seizure frequency per 28 days was not reached for EPIDIOLEX 10 mg/kg/day, EPIDIOLEX 20 mg/kg/day, or placebo in Trial 1; was not reached for EPIDIOLEX 10 mg/kg/day or EPIDIOLEX 20 mg/kg/day and was 56 days for placebo in Trial 2; and was not reached for EPIDIOLEX 10 mg/kg/day, was 84 days for EPIDIOLEX 20 mg/kg/day, and was not reached for placebo in Trial 3.

12.2 Seizures Associated with Tuberous Sclerosis Complex

The efficacy of EPIDIOLEX as adjunctive therapy for the treatment of seizures associated with tuberous sclerosis complex was established in 2 randomized, double-blind, placebo-controlled clinical trials (Trial 4 and Trial 5) in patients 1 to 23 years of age. Patients had a diagnosis of tuberous sclerosis complex and uncontrolled seizures despite treatment with concomitant antiepileptic drugs.

Trial 4 (Study 4) was a 16-week trial that randomized 148 patients to receive EPIDIOLEX 25 mg/kg/day, EPIDIOLEX 50 mg/kg/day, or placebo. Patients had a mean baseline frequency of 85.2 seizures per 28 days. The primary endpoint was the change from baseline in seizure frequency per 28 days. Trial 5 (Study 5) was a 16-week trial that randomized 224 patients to receive EPIDIOLEX 25 mg/kg/day, EPIDIOLEX 50 mg/kg/day, or placebo. Patients had a mean baseline frequency of 76.2 seizures per 28 days. The primary endpoint was the change from baseline in seizure frequency per 28 days.

The addition of EPIDIOLEX 25 mg/kg/day or EPIDIOLEX 50 mg/kg/day to concomitant antiepileptic drugs resulted in a greater reduction in seizure frequency per 28 days compared to placebo. The median percent reduction from baseline in seizure frequency per 28 days was 30% for EPIDIOLEX 25 mg/kg/day, 48% for EPIDIOLEX 50 mg/kg/day, and 12% for placebo in Trial 4; and 27% for EPIDIOLEX 25 mg/kg/day, 46% for EPIDIOLEX 50 mg/kg/day, and 14% for placebo in Trial 5. The median reduction in seizure frequency per 28 days was statistically significantly greater for EPIDIOLEX 50 mg/kg/day than placebo in Trial 4 and Trial 5.

The percentage of patients who had a reduction in seizure frequency per 28 days of 50% or greater was 26% for EPIDIOLEX 25 mg/kg/day, 50% for EPIDIOLEX 50 mg/kg/day, and 19% for placebo in Trial 4; and 28% for EPIDIOLEX 25 mg/kg/day, 40% for EPIDIOLEX 50 mg/kg/day, and 15% for placebo in Trial 5. The median treatment duration was 15 weeks for EPIDIOLEX 25 mg/kg/day, 15 weeks for EPIDIOLEX 50 mg/kg/day, and 15 weeks for placebo in Trial 4; and 15 weeks for EPIDIOLEX 25 mg/kg/day, 15 weeks for EPIDIOLEX 50 mg/kg/day, and 15 weeks for placebo in Trial 5.

Figure 3: Percent Reduction in Seizure Frequency per 28 Days in Patients with Seizures Associated with Tuberous Sclerosis Complex Treated with Adjunctive EPIDIOLEX 25 mg/kg/day, EPIDIOLEX 50 mg/kg/day, or Placebo

12.3 Lennox-Gastaut Syndrome

The efficacy of EPIDIOLEX as adjunctive therapy for the treatment of seizures associated with Lennox-Gastaut syndrome was established in 3 randomized, double-blind, placebo-controlled clinical trials (Trial 6, Trial 7, and Trial 8) in patients 2 to 55 years of age. Patients had a diagnosis of Lennox-Gastaut syndrome and uncontrolled seizures despite treatment with concomitant antiepileptic drugs.

Trial 6 (Study 6) was a 14-week trial that randomized 225 patients to receive EPIDIOLEX 10 mg/kg/day, EPIDIOLEX 20 mg/kg/day, or placebo. Patients had a mean baseline frequency of 85.0 drop seizures per 28 days. The primary endpoint was the change from baseline in drop seizure frequency per 28 days. Trial 7 (Study 7) was a 14-week trial that randomized 171 patients to receive EPIDIOLEX 10 mg/kg/day, EPIDIOLEX 20 mg/kg/day, or placebo. Patients had a mean baseline frequency of 74.4 drop seizures per 28 days. The primary endpoint was the change from baseline in drop seizure frequency per 28 days. Trial 8 (Study 8) was a 19-week trial that randomized 263 patients to receive EPIDIOLEX 10 mg/kg/day, EPIDIOLEX 20 mg/kg/day, or placebo. Patients had a mean baseline frequency of 90.2 drop seizures per 28 days. The primary endpoint was the change from baseline in drop seizure frequency per 28 days.

The addition of EPIDIOLEX 10 mg/kg/day or EPIDIOLEX 20 mg/kg/day to concomitant antiepileptic drugs resulted in a greater reduction in drop seizure frequency per 28 days compared to placebo. The median percent reduction from baseline in drop seizure frequency per 28 days was 37% for EPIDIOLEX 10 mg/kg/day, 41% for EPIDIOLEX 20 mg/kg/day, and 22% for placebo in Trial 6; 30% for EPIDIOLEX 10 mg/kg/day, 44% for EPIDIOLEX 20 mg/kg/day, and 14% for placebo in Trial 7; and 19% for EPIDIOLEX 10 mg/kg/day, 34% for EPIDIOLEX 20 mg/kg/day, and 13% for placebo in Trial 8. The median reduction in drop seizure frequency per 28 days was statistically significantly greater for EPIDIOLEX 20 mg/kg/day than placebo in Trial 6 and Trial 7. The median reduction in drop seizure frequency per 28 days was statistically significantly greater for EPIDIOLEX 10 mg/kg/day than placebo in Trial 7.

The percentage of patients who had a reduction in drop seizure frequency per 28 days of 50% or greater was 24% for EPIDIOLEX 10 mg/kg/day, 32% for EPIDIOLEX 20 mg/kg/day, and 14% for placebo in Trial 6; 23% for EPIDIOLEX 10 mg/kg/day, 33% for EPIDIOLEX 20 mg/kg/day, and 9% for placebo in Trial 7; and 15% for EPIDIOLEX 10 mg/kg/day, 26% for EPIDIOLEX 20 mg/kg/day, and 12% for placebo in Trial 8. The median treatment duration was 15 weeks for EPIDIOLEX 10 mg/kg/day, 15 weeks for EPIDIOLEX 20 mg/kg/day, and 15 weeks for placebo in Trial 6; 15 weeks for EPIDIOLEX 10 mg/kg/day, 15 weeks for EPIDIOLEX 20 mg/kg/day, and 15 weeks for placebo in Trial 7; and 15 weeks for EPIDIOLEX 10 mg/kg/day, 15 weeks for EPIDIOLEX 20 mg/kg/day, and 15 weeks for placebo in Trial 8.

Figure 4: Percent Reduction in Drop Seizure Frequency per 28 Days in Patients with Lennox-Gastaut Syndrome Treated with Adjunctive EPIDIOLEX 10 mg/kg/day, EPIDIOLEX 20 mg/kg/day, or Placebo

13 HOW SUPPLIED/STORAGE AND HANDLING

13.1 How Supplied

EPIDIOLEX (cannabidiol) oral solution is supplied as a clear to slightly hazy, colorless to slightly yellow solution in a 4 fluid ounce (118 mL) amber bottle with a child-resistant closure. Each bottle contains 118 mL of EPIDIOLEX and is packaged with a 5 mL oral dosing syringe graduated in 0.1 mL increments.

NDC 42291-100-04

13.2 Storage and Handling

Store EPIDIOLEX at 20°C to 25°C (68°F to 77°F). Excursions permitted between 15°C and 30°C (59°F and 86°F).

14 PATIENT COUNSELING INFORMATION

Advise patients to read the FDA-approved patient labeling (Patient Information).

Hepatotoxicity

Inform patients that EPIDIOLEX may cause liver injury. Advise patients to report symptoms of liver injury, such as fatigue, anorexia, right upper abdominal discomfort, jaundice, dark urine, or bleeding or bruising.

Concomitant use with Valproate

Inform patients that concomitant use of EPIDIOLEX with valproate may increase the risk of liver injury. Advise patients to report symptoms of liver injury.

Somnolence and Sedation

Inform patients that EPIDIOLEX may cause somnolence and sedation. Advise patients not to drive or operate machinery until they have gained sufficient experience on EPIDIOL
